

Doctor Dev

Find repository risks before they reach developers

A connected health check for tests, configuration and release readiness

TestPilot

ConfigDoctor

The repo can look healthy while its parts disagree

A passing test suite and valid config files do not expose every cross-file risk.

01 Untested behavior

A route exists, but its error or authorization path lacks test evidence.

02 Configuration drift

Code, environment templates, Docker, CI and README disagree.

03 Slow triage

Separate warnings leave developers to connect the evidence manually.

One scan connects the evidence

Submit a public GitHub URL or an approved local path; Doctor Dev builds an actionable report.

01

SCAN

Files, stack, routes and test assets

02

DIAGNOSE

TestPilot finds test gaps.
ConfigDoctor detects drift.

03

ACT

Review severity, confidence, evidence and a concrete next step.

Read-only analysis · Markdown and JSON export · Optional starter tests

A real repository scan reveals the gaps

Example shown: the public Axios repository, as captured in the supplied product screenshots.

88

/100 health score

4 test gaps

3 configuration issues

Evidence based coverage label when no numeric report exists

Two focused diagnostic engines

Each finding points back to repository evidence and states how confident the analysis is.

TestPilot

Maps tests to source and routes

Highlights missing error, edge and authorization cases. Reads numeric coverage only when a supported artifact exists.

ConfigDoctor

Cross-checks the whole setup

Compares environment variables, Docker, ports, CI, runtime metadata and README instructions.

A finding you can act on

The report identifies the file, issue and recommended change.

README port mismatch

Doctor Dev flags ports documented in the README that the application does not use.

The same scan also notes a missing .env.example and absent test instructions.

Built with IBM Bob 2.0

Bob helped reason across the repository, from analyzer logic through UI, security and review.

Architecture

TestPilot, ConfigDoctor and shared backend types

Implementation

Repository discovery, AST analysis and evidence mapping

Hardening

False-positive debugging, path safety and regression review
